# Package 'LESYMAP'

November 5, 2017

| Title Leions to Symptom Mapping in R  |  |
|---|--|
| Version 0.0.0.9007  |  |
| <b>Date</b> 2017-10-26  |  |
| Description LESYMAP maps the specific brain areas responsible for cognitive deficits by taking a series of lesion maps and a vector of behavioral scores. Both univariate (t-test, Brunner-Munzel, regression) and multivariate (sparse canonical corelations) tests are available. LESYMAP is built to run both real and simulated lesion-to-symptom mapping analyses. |  |

.createFolds

createFolds

### Description

Used to create folds for k-fold validation

### Usage

```
.createFolds(y, k = 10, list = TRUE, returnTrain = FALSE)
```

### Arguments

y split sample by balancing y

k number of folds

list logical whether to return folds in a list

returnTrain logical whether to return training indices (T) or the test samples (F)

### Author(s)

Caret Package

BM 3

ВМ

Massive Brunner-Munzel tests

### **Description**

Takes a binary matrix of voxels and a vector of behavior and runs Brunner-Munzel tests on each voxel. This function is not compiled and is slow.

### Usage

```
BM(lesmat, behavior)
```

### **Arguments**

lesmat matrix of voxels
behavior vector of behavior

#### Value

Returned list with:

- statistic statistical values
- dof degrees of freedom

### Author(s)

Dorian Pustina

### **Examples**

```
set.seed(123)
lesmat = matrix(rbinom(200,1,0.5), ncol=2)
set.seed(123)
behavior = rnorm(100)
result = BM(lesmat, behavior)
```

BMfast

Fast Brunner-Munzel tests (v1)

### Description

Takes a binary matrix of voxels and a vector of behavior and runs Brunner-Munzel tests on each voxel. This is a fast function, but may produce infinite values for perfectly separated group. Use BMfast2 which avoids this problem.

```
BMfast(X, y)
```

4 BMfast2

### **Arguments**

X binary matrix ov voxlels (columns) for all subjects (rows)

y vector of behavioral scores.

#### Value

List with two vectors: - statistic - BM values - dfbm - degrees of freedom

### Author(s)

Dorian Pustina

/@export

BMfast2

Fast Brunner-Munzel tests (v2)

### **Description**

Takes a binary matrix of voxels and a vector of behavior and runs Brunner-Munzel tests on each voxel. This is a fast function that corrects for infinite values with a similar approach as the nparcomp package.

### Usage

```
BMfast2(X, y, computeDOF = TRUE)
```

### **Arguments**

X binary matrix ov voxlels (columns) for all subjects (rows)

y vector of behavioral scores.

computeDOF (true) chooses whether to compute degrees of freedom. Set to false to save time

during permutations.

### Value

List with two vectors:

- statistic BM values
- dfbm degrees of freedom

### Author(s)

Dorian Pustina

BMperm 5

### **Examples**

```
set.seed(1234)
lesmat = matrix(rbinom(40,1,0.2), ncol=2)
set.seed(1234)
behavior = rnorm(20)
test = LESYMAP::BMfast2(lesmat, behavior)
test$statistic[,1] # -2.0571825 -0.8259754
test$dfbm[,1] # 16.927348 7.563432
```

 ${\tt BMperm}$ 

Fast Brunner-Munzel tests (v2) with permutations

### Description

Takes a binary matrix of voxels and a vector of behavior and runs Brunner-Munzel tests on each voxel. This is a fast function that corrects for infinite values with a similar approach as the nparcomp package. It calculates p-values by running permutations of each voxel and using the ratio of times the real BM score exceeds the permuted BM score.

### Usage

```
BMperm(X, y, computeDOF = TRUE, npermBM = 20000L, alternative = 1L)
```

#### **Arguments**

| X           | binary matrix ov voxlels (columns) for all subjects (rows)   |
|-------------|--|
| У           | vector of behavioral scores.   |
| computeDOF  | (default true) chooses whether to compute degrees of freedom. Set to false to save time during permutations. |
| npermBM     | (default 20000) number of permutations to run at each voxel  |
| alternative | (default 1) integer to select the tail of pvalues. 1-greater, 2-less, 3-two.sided                            |

#### Value

List with these objects:

- statistic BM values
- dfbm degrees of freedom
- pvalue permutation-based probability value

### Author(s)

Dorian Pustina

6 checkAntsInput

#### **Examples**

```
set.seed(1234)
lesmat = matrix(rbinom(40,1,0.2), ncol=2)
set.seed(1234)
behavior = rnorm(20)
test = LESYMAP::BMperm(lesmat, behavior, alternative=3)
test$statistic[,1] # -2.0571825 -0.8259754
test$dfbm[,1] # 16.927348  7.563432
test$pvalue[,1] # 0.1427929 0.4102795
```

checkAntsInput

checkAntsInput

### **Description**

Function to check a variable whether is composed of an antsImage, list of antsImages, or simply filenames. If none of the above, an error is returned.

#### Usage

```
checkAntsInput(input, checkHeaders = F)
```

### **Arguments**

```
input the variable to be checked checkHeaders make sure all images have the same headers
```

### Value

Type of variable (antsImage, antsImageList, antsFiles) or error if variable cannot be established.

#### Author(s)

Dorian Pustina

```
## Not run:
    files = Sys.glob('/data/jag/nifti/*.nii.gz')
    myimagelist = imageFileNames2ImageList(files)
    checkAntsInput(myimagelist) # returns 'antsImageList'
    checkAntsInput(antsFiles) # returns 'antsFiles'
    checkAntsInput(myimagelist[[1]]) # returns 'antsImage'
## End(Not run)
```

checkFilenameHeaders 7

checkFilenameHeaders

checkFilenameHeaders

### **Description**

Function to check that all filenames in a vector point to existing files with the same resolution, orientation, size, and origin.

#### Usage

```
checkFilenameHeaders(files, showError = T)
```

#### **Arguments**

files character vector of filenames

showError logical whether to show an error (True) or to return a boolean instead. Returned

values are True=pass,False=Fail

#### Value

logical if the test was successful or not

#### Author(s)

Dorian Pustina

checkImageList checkImageList

### Description

Function to check that all antsImages in a list have the same orientation, origin, and resolution. The function stops with an error if one of the images has unusual headers. This behavior can be overcome by setting showError=F, and using the returned status (True=pass, False=fail) to make decisions outside this function.

#### Usage

```
checkImageList(imgList, showError = T, binaryCheck = F)
```

### **Arguments**

imgList list of antsImages

showError boolean indicating whether to show the exact error and interrupt the function

(TRUE, default), or don't show the error and return the check status (FALSE).

The returned values when showError=F are T=passed or F=Failed.

binaryCheck boolean, check if images are binary (0/1 values). Useful when checking masks

or lesions. This check slows the output of the function.

8 checkMask

#### Value

True if list has images with same headers, otherwise False.

### Author(s)

Dorian Pustina

### **Examples**

```
## Not run:
files = Sys.glob('/data/jag/nifti/*.nii.gz')
myimagelist = imageFileNames2ImageList(files)
checkImageList(myimagelist) # no value returned
checkImageList(lesions, showError=F) # True returned
myimagelist[[4]] = cropIndices(myimagelist[[4]], c(1,1,1), c(20,20,20))
checkImageList(myimagelist) # error on image 4
## End(Not run)
```

checkMask

checkMask

### **Description**

Function to check if mask is in the same space as inputs

### Usage

```
checkMask(lesions.list, mask)
```

### **Arguments**

```
lesions.list list of antsImages or character vector of filenames
mask antsImage of mask to check
```

### Value

Nothing is returned, function stops with error if mask is not in the same space as images in lesions.list

#### Author(s)

Dorian Pustina

getLesionLoad 9

| getLesionLoad |
|---------------|
|---------------|

#### **Description**

Computes lesion loads from a series of images. A parcellation image (or simple mask) is required to define the regions from which to compute the lesion load.

#### Usage

```
getLesionLoad(lesions.list, parcellation, label = NA, mask = NA,
binaryCheck = F, keepAllLabels = F, minSubjectPerLabel = "10%")
```

#### **Arguments**

```
lesions.list list of antsImages or filenames. Must be binary (0 and 1 values).
parcellation ansImage or filename of the parcellated volumes. A parcellation is an image
                  brain regions showned as with integer values (i.e. ,1,2,3,...).
label
                  (default=NA) you can ask to get output for a specific label in the parcellation
                  volume (i.e., label=122).
                  (default=NA) if this mask is specified (antsImage or filename) lesioned voxels
mask
                  outside the mask are ignored. This is not a good choice, but in case you need it
                  its there.
                  (default=FALSE) check whether lesion maps are binary (0/1). Will output an
binaryCheck
                  error if lesion files are not binary.
keepAllLabels
                  (default=FALSE) by default labels are removed if affected in just few subjects.
                  Setting this to TRUE will keep all labels.
minSubjectPerLabel
                  minimum number of subjects a parcel must be lesioned to keep and return it.
```

#### Value

• outputMatrix of lesion loads between 0 and 1. 1 means 100% lesioned. Each column is a single parcel and each row a single subject. Parcel numbers are placed as column names.

### Author(s)

Dorian Pustina

```
lesydata = file.path(find.package('LESYMAP'),'extdata')
filenames = Sys.glob(file.path(lesydata, 'lesions', '*.nii.gz'))
lesions = imageFileNames2ImageList(filenames[1:10])
parcellation = antsImageRead(
file.path(lesydata,'template', 'Parcellation_403areas.nii.gz'))
lesload = getLesionLoad(lesions, parcellation)
```

getLesionSize

getLesionSize

#### **Description**

Compute lesion sizes from a list of antsImages.

#### Usage

```
getLesionSize(lesions.list)
```

#### **Arguments**

lesions.list List of antsImages. For proper measurement, images must be binary.

#### Value

vector of lesion sizes

#### Author(s)

**Dorian Pustina** 

```
getUniqueLesionPatches
```

Unique Lesion Patches

### **Description**

Compute unique patches of voxels with the same pattern of lesions in all subjects. Useful to understand the number of patterns that will be analyzed in a lesion dataset. A patch is a group of voxels, not necessarily close to each other, which have the same identical lesion pattern.

### Usage

```
getUniqueLesionPatches(lesions.list, mask = NA, returnPatchMatrix = F,
    thresholdPercent = 0.1, binaryCheck = F, showInfo = T)
```

#### **Arguments**

lesions.list list of antsImages (faster) or filenames (slower)

 ${\tt mask}$ 

(default=NA) a mask image to restrict the search for patches. Will be automatically calculated if not provided. Normally the mask restricts the search only to voxels lesioned in >10% of subejcts. To set this proportion use thresholdPercent.

returnPatchMatrix

(default=FALSE) logical, should the matrix of patches be returned. This is used in lesymap to run the analyses.

thresholdPercent

(default=0.1) voxels with lesions in less than this proportion of subjects will not be considered. I.e., 0.1 = 10%.

lesyload\_mricron 11

```
binaryCheck (default=FALSE) set this to TRUE to verify that maps are binary.

showInfo (default=TRUE) logical indicating whether to display information.
```

#### Value

List of objects named as follows:

- patchimg antsImage with every voxel assigned a patch number
- patchimg.samples antsImage mask of one representative voxel for each patch. Can be used to extract the patchmatrix.
- patchimg.size antsImage with the patch size at every voxel
- patchimg.mask antsImage of the mask used to extract patches. Can be used to put back results when combined with patchindx.
- patchindx vector of patch membership for each voxel. Can be used to put back results in an image.
- npatches number of unique patches in the image
- nvoxels total number of lesioned voxels in patching.mask
- patchvoxels vector of voxel count for each patch
- patchvolumes vector of volume size for each patch
- patchmatrix matrix of patches. This is used in lesymap to save time when running repetitive analyses.

#### Author(s)

Dorian Pustina

### Examples

```
lesydata = file.path(find.package('LESYMAP'), 'extdata')
filenames = Sys.glob(file.path(lesydata, 'lesions', '*.nii.gz'))
patchinfo = getUniqueLesionPatches(filenames[1:10]) # slower
lesions = imageFileNames2ImageList(filenames[1:10])
patchinfo = getUniqueLesionPatches(lesions) # faster
```

```
lesyload_mricron lesyload_mricron
```

### **Description**

Function to load data from a previous analysis in MRIcron/npm in a ready format for use in lesymap

```
lesyload_mricron(valfile, imageFolder = NA, returnFilenames = F,
  checkHeaders = T, showInfo = T)
```

### Arguments

valfile

mricron filename with extention \*.val. The function will search for images in the same folder where valfile is located, unless you specify <code>imageFolder</code>. If any of the files listed in the .val file are not found in the folder, an error will be displayed.

imageFolder (default=NA) folder to look for the image files

returnFilenames

(default=FALSE) By default the function will load the images in memory to speed up things in lesymap. This may require too much RAM memory in some cases, and you may want to use filenames instead, which requires less memory but is slower in lesymap.

 $\verb|checkHeaders| (default=TRUE)| Headers| will be checked to make sure all images have the same$ 

dimension/origin/resolution, etc.

showInfo (default=TRUE) show information upon successful load

#### Value

List with the following information lesions - list of antsImages or vector of filenames behavior - vector of behavioral scores

#### Author(s)

Dorian Pustina

lesymap

Lesion to Symptom Mapping

#### **Description**

Lesymap uses univariate and multivariate methods to map functional regions of the brain that, when lesioned, cause specific cognitive deficits. All is required is a set of Nifti images with the lesion of each subject and the vector of behavioral scores. Lesions must be already registered in template space, use 'antsRegistration' or other ANTs tools to achieve this. Lesymap will check that lesions are in the same space before running. By default, voxels with identical lesion patterns are grouped together in unique patches, and analysis are run on patches. Patch-based mapping decreases the number of multiple comparisons and speeds up the analyses. Multivariate mapping is performed using an optimized version of sparse canonical correlations (SCCAN).

```
lesymap(lesions.list, behavior, mask = NA, patchinfo = NA, method = "BM",
   correctByLesSize = "none", multipleComparison = "fdr",
   pThreshold = 0.05, flipSign = F, minSubjectPerVoxel = "10%",
   nperm = 1000, saveDir = NA, binaryCheck = F, noPatch = F,
   showInfo = T, ...)
```

#### **Arguments**

lesions.list list of antsImages, or a vector of filenames, or a single antsImage with 4 dimensions

behavior vector of behavioral scores or filename pointing to a file with a single column of

numbers.

mask (default=NA) binary image to select the area where analysis will be performed.

If not provided will be computed automatically by thresholding the average le-

sion map at minSubjectPerVoxel.

patchinfo (default=NA) an object obtained with getUniqueLesionPatches or from a previ-

ous analyses. Useful for repetitive analysis to save time and avoid the computa-

tion of patches each time.

what tests to run, one of 'BM' (default), 'BMfast', 'ttest', 'welch', 'regres', 'regresfast', 'regresPerm', 'sccan', 'sccanRaw'.

BM - Brunner-Munzel non parametric test, also called the Generalized Wilcoxon Test. The BM test is the same test used in the npm/Mricron software. See (see Rorden (2007)).

BMfast - ultrafast Brunner-Munzel with compiled code. BMfast can be combined with multipleComparison='FWERperm' to perform permutation based thresholding in a short time.

ttest - Regular single tailed t-test. Variances of groups are assumed to be equal. This is the test used in the voxbo software. Relies on t.test function in R. It is assumed that 0 voxels are healthy, i.e., higher behavioral scores. See the alternative parameter for inverted cases. (see Bates (2003)).

welch - t-test that assumes unequal variance between groups. Relies on t.test function in R.

regres - linear model between voxel values and behavior. Uses the lm function in R. This is equivalent to a t-test, but is useful when voxel values are continuous. To model the effect of covariates use the "regresfast" method

regressast - ultrafast linear regressions with compiled code. This method allows setting covariates. If covariates are specified the effect of each voxel will be estimated with the formula:

behavior ~ voxel + covar1 + covar2 + ...

This method allows multiple comparison correction with permutation based methods "FWERperm" and "clusterPerm". If these corrections are required and covariates are specified, the effect of each voxel is established with the Freedman-Lane method (see Winkler (2014)).

regresPerm - linear model between voxel values and behavior. The p-value of each individual voxel us established by permuting voxel values. The lmPerm package is used for this purpose. Note, these permutations do not correct for multiple comparisons, they only establish voxel-wise p-values.

chisq-chi-square test between voxel values and behavior. The method is used when behavioral scores are binary (i.e. presence of absence of deficit). Relies on the chisq.test R function. By default this method corrects individual voxel p-values with the Yates method (the same approach offered in the Voxbo software).

 ${\tt chisqPerm}$  - chi-square tests. P-values are established through permutation tests instead of regular statistics. Relies on the  ${\tt chisq.test}$  R function.

sccan - sparse canonical correlations (NEW). Multivariate method that considers all voxels at once. By default, lesymap will run a lengthy procedure to

method

determine the optimal sparseness value (how extensive the results should be). You can set optimizeSparseness=FALSE if you want to skip this optimization. The search for optimal sparsness provides a cross-validated correlation measure that shows how well the sparseness value can predict new patients. If this predicive correlation is below significance (i.e., below pThreshold), the entire solution will be ignored and a NULL result will be returned. Lesymap returns normalized (0-1) voxel weights converted to positive; you can use rawStat=TRUE to retain the original voxel weights. Note that both lesion and behavior data are scale and centered before running SCCAN (hardcoded in lsm\_sccan). You must apply the same scaling if you were to predict behavioral scores with the obtained voxel weights.

correctByLesSize

whether to correct for lesion size in the analysis. Options are "none", "voxel", "behavior":

- "none": (default) no correction
- "voxel": divide voxel values by 1/sqrt(lesionsize). This is the method used in Mirman (2015) and Zhang (2014). This correction works only with 'regres' methods. Two sample comparisons (t-tests and Brunner-Munzel) use binary voxels and will ignore this correction.
- "behavior": residualize behavioral scores by removing the effect of lesion size. This works on all methods, but is more agressive on results.

multipleComparison

(default='fdr') method to adjust p-values. Standard methods include "holm", "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr". (see p.adjust)

Permutation methods include:

"FWERperm" (permutation based family-wise threshold) is enabled with methods 'BMfast' and 'regresfast'. In this case, many analysis are run with permuted behavioral scores, and the peak score is recorded each time (see Winkler 2014). The optimal threshold is established at 95th percentile of this distribution (or whatever pThreshold you choose). You can choose to use as reference another voxel lower in the ranks by specifying another 'v' value (i.e., lesymap(..., v=10) will record the 10th highest voxel).

"clusterPerm" (permutation based cluster correction) is enabled for 'regresfast'. It records the maximal cluster size from many random permutations of the behavior score and sets a cluster threshold based on that distribution. You must select pThreshold (voxel-wise, default=0.05) and clusterPermThreshold (cluster-wise, default 0.05) to achieve optimal with this method.

pThreshold

(default=0.05) threshold statistics at this p-value (after corrections or permutations)

flipSign

 $logical\ (default\mbox{=}FALSE), invert\ the\ sign\ in\ the\ statistics\ image.$ 

minSubjectPerVoxel

(default='10%') remove voxels/patches with lesions in less than X subjects. Value can be speficifed as percentage ('10%') or exact number of subjects (10).

nperm

(default=1000) number of permutations to run when necessary.

saveDir

(default=NA) save results in the specified folder.

binaryCheck

logical (default=FALSE), make sure the lesion matrix is 0/1.

noPatch

logical (default=FALSE), if True avoids using patch information and will analyze all voxels. It will take longer and results will be worse due to more multiple comparison corrections. This argument is ignored when performing SCCAN analyses.

showInfo logical (default=TRUE), display time-stamped info messages
... arguments that will be passed down to other functions (i.e., sparsness=0.045)

#### **Details**

Several other parameters can be specified to lesymap() which will be passed to other called fuctions. Here are some examples:

permuteNthreshold - (default=9) for Brunner-Munzel tests only. Voxels lesioned in less than this number of subjects will undergo permutation-based p-value estimation. Useful because the BM test is not valid when comparing groups with N < 9. Note, permuted BM tests currently require the package 'nparcomp'.

clusterPermThreshold - threshold used to find the optimal cluster size when using 'cluster-Perm' multiple comparison correction.

alternative - (default='greater') for two sample tests (ttests and BM). By default LESYMAP computes single tailed p-values assuming that non-lesioned 0 voxels have higher behavioral scores. You can specify the opposite relationship with alternative='less' or compute two tailed p-values with alternative='two.sided'.

covariates - (default=NA) enabled for method = 'regresfast'. This will allow to model the effect of each voxel in the context of other covariates, i.e., formula "behavior  $\sim$  voxel + covar1 + covar2 + ...".

I,.e., lesymap(lesions,behavior, method='regresfast', covariates=cbind(lesionsize, age)).

If you choose permutation based thresholding with covariates, lesymap will use the Freedman-Lane method for extracting the unique effect of each voxel (see Winkler 2014, Freedman 1983)

template - antsImage or filename used for plotting the results if a saving directory is specified (see saveDir)

v - (default=1) which voxel to record for permutation based thresholding. Normally the peak voxel is used (1), but other voxels can be recorded. See Mirman 2017 for this approach.

### Value

The following objects are typically found in the returned list:

- stat.img statistical map
- pval.img p-values map
- zmap.img zscore map
- mask.img mask used for the analyses
- average.img map of all lesions averaged. Map is produced only if no mask is defined.
- callinfo list of details of how you called lesymap
- perm.vector the values obtained from each permutation
- perm.clusterThreshold threshold computed for cluster thresholding
- perm.FWERthresh threshold computed for FWERperm thresholding
- patchinfo list of variables describing patch information:
  - patchimg antsImage with the patch number each voxels belongs to
  - patchimq.samples antsImage mask with a single voxel per patch
  - patchimg.size antsImage with the patch size at each voxel
  - patchimg.mask the mask within which the function will look for patches
  - npatches number of unique patches in the image

16 lsm\_BM

- nvoxels total number of lesioned voxels in mask
- patchvoxels vector of voxel count for each patch
- patchvolumes vector of volume size for each patch
- patchmatrix the lesional matrix, ready for use in analyses. Matrix has size NxP (N=number of subjects, P=number of patches)

#### Author(s)

**Dorian Pustina** 

### **Examples**

```
lesydata = file.path(find.package('LESYMAP'),'extdata')
filenames = Sys.glob(file.path(lesydata, 'lesions', 'Subject*.nii.gz'))
behavior = Sys.glob(file.path(lesydata, 'behavior', 'behavior.txt'))
template = antsImageRead(
    Sys.glob(file.path(lesydata, 'template', 'ch2.nii.gz')))
lsm = lesymap(filenames, behavior, method = 'BMfast')
plot(template, lsm$stat.img, window.overlay = range(lsm$stat.img))

## Not run:
# Same analysis with SCCAN
lsm = lesymap(filenames, behavior, method = 'sccan',
sparseness=0.045, optimizeSparseness=FALSE)
plot(template, lsm$stat.img, window.overlay = range(lsm$stat.img))
save.lesymap(lsm, saveDir='/home/dp/Desktop/SCCANresults')

## End(Not run)
```

 $lsm_BM$ 

lsm\_BM

### **Description**

Lesion to symptom mapping performed on a prepared matrix. Brunner-Munzel tests are performed using each column of the matrix to split the behavioral scores in two groups.

#### Usage

```
lsm_BM(lesmat, behavior, permuteNthreshold = 9, nperm = 10000,
alternative = "greater", showInfo = TRUE, ...)
```

### **Arguments**

nperm

Number of permutations to perform when needed.

Ism\_BMfast 17

```
alternative (default="greater") It is assumed that healthy voxels (0) have greater behavioral scores. If your data follow an inverted relationship choose "less" or "two.sided". showInfo display info messagges when running the function.

... other arguments received from lesymap.
```

#### Value

List of objects returned:

- statistic vector of statistical values
- pvalue vector of pvalues
- zscore vector of zscores

#### Author(s)

Dorian Pustina

#### **Examples**

```
{
set.seed(123)
lesmat = matrix(rbinom(200,1,0.5), ncol=2)
set.seed(123)
behavior = rnorm(100)
result = lsm_BM(lesmat, behavior)
}
```

lsm\_BMfast

lsm\_BMfast

#### **Description**

Lesion to symptom mapping performed on a prepared matrix. Brunner-Munzel tests are performed using each column of the matrix to split the behavioral scores in two groups. This function relies on a compiled version for fast processing.

### Usage

```
lsm_BMfast(lesmat, behavior, permuteNthreshold = 9, alternative = "greater",
  statOnly = FALSE, nperm = 1000, npermBM = 20000, FWERperm = FALSE,
  v = 1, pThreshold = 0.05, permuteAllVoxelsBM = FALSE,
  showInfo = FALSE, ...)
```

#### **Arguments**

```
lesmat binary matrix (0/1) of voxels (columns) and subjects (rows). behavior vector of behavioral scores. permuteNthreshold
```

(default=9) Voxels lesioned in less than this number will undergo permutation based thresholding. See Medina et al 2010.

18 Ism\_BMfast

| alternative                | (default="greater") It is assumed that healthy voxels (0) have greater behavioral scores. If your data follow an inverted relationship choose "less" or "two.sided".   |
|----------------------------|--|
| statOnly                   | logical (default=FALSE), skips some computations, mostly for internal use to speed up some things.   |
| nperm                      | (default=1000) Number of permutations to perform on entire volumes when needed for multiple comparisons corrections (i.e., in FWERperm).   |
| npermBM                    | (default=20000) Number of permutations to perform at every single voxel below permuteNthrehsold. Note, this argument is different from nperm, which controls volume-based permutations to perform multiple comparison corrections with FWERperm.       |
| FWERperm                   | logical (default=FALSE) whether to perform permutation based FWER thresholding.  |
| V                          | (default=1) which voxel to record at each permutation with FWERperm. All software use the peak voxel (v=1), but you can choose a voxel further down the list to relax the threshold (i.e., v=10 for 10 highest voxel) (see Mirman (2017)).             |
| pThreshold<br>permuteAllVo | (default=0.05) what threshold to use for FWER xelsBM   |
| -                          | (default=FALSE) whether to force the permutation-based p-value calulation for all voxels, instead of applying only to voxels below permuteNthrehsold. Setting this option to TRUE will force all voxels undergo permutation-based p-value calculation. |
| showInfo                   | display info messagges when running the function.  |
|                            | other arguments received from lesymap.   |

### Value

### List of objects returned:

- statistic vector of statistical values
- pvalue vector of pvalues
- zscore vector of zscores
- perm.vector (optional) vector of permuted statistics
- perm.FWERthresh (optional) permutation threshold established from the distribution of perm.vector

### Author(s)

### Dorian Pustina

Note on zscores quorm gives same values as MRIcron and relies on the normal distribution. however, we are computing t-scores, and should have relied on that distribution, which is the t-score itself.

```
{
set.seed(123)
lesmat = matrix(rbinom(200,1,0.5), ncol=2)
set.seed(123)
behavior = rnorm(100)
result = lsm_BMfast(lesmat, behavior)
}
```

lsm\_chisq 19

#### **Description**

Lesion to symptom mapping performed on a prepared matrix. The behavior must be a binary vector. Chi square tests are performed at each voxel. By default the Yates correction is performed, use correct=FALSE if you need to disable it. The behavior must be a binary vector. Exact p-values can be obtained with permutation based estimatins.

### Usage

```
lsm_chisq(lesmat, behavior, YatesCorrect = TRUE, runPermutations = F,
   nperm = 2000, showInfo = TRUE, ...)
```

### **Arguments**

#### Value

List of objects returned:

- statistic vector of statistical values
- pvalue vector of pvalues
- zscore vector of zscores

#### Author(s)

Dorian Pustina

```
{
set.seed(123)
lesmat = matrix(rbinom(200,1,0.5), ncol=2)
set.seed(1234)
behavior = rbinom(100,1,0.5)
result = lsm_chisq(lesmat, behavior)
}
```

lsm\_regres

### Description

Lesion to symptom mapping performed on a prepared matrix. Regressions are performed between behavior and each column in the lesmat matrix.

### Usage

```
lsm_regres(lesmat, behavior)
```

### Arguments

lesmat matrix of voxels (columns) and subjects (raws).

behavior vector of behavioral scores.

### Value

List of objects returned:

- statistic vector of statistical values
- pvalue vector of pvalues
- zscore vector of zscores

### Author(s)

Dorian Pustina

```
{
set.seed(123)
lesmat = matrix(rbinom(200,1,0.5), ncol=2)
set.seed(123)
behavior = rnorm(100)
result = lsm_regres(lesmat, behavior)
}
```

lsm\_regresfast 21

### Description

Lesion to symptom mapping performed on a prepared matrix. Regressions are performed between behavior and each column of the lesmat matrix. Fast function based on compiled code.

### Usage

```
lsm_regresfast(lesmat, behavior, covariates = NA, FWERperm = F,
   nperm = 1000, v = 1, pThreshold = 0.05, clusterPerm = F, mask = NA,
   voxindx = NA, samplemask = NA, clusterPermThreshold = 0.05,
   showInfo = T, ...)
```

#### **Arguments**

| lesmat               | matrix of voxels (columns) and subjects (rows).   |
|----------------------|---|
| behavior             | vector of behavioral scores.  |
| covariates           | (default=NA) vector of matrix of covariates.  |
| FWERperm             | logical (default=FALSE) whether to run permutation based FWER thresholding.               |
| nperm                | Number of permutations to perform when needed.  |
| V                    | (default=1) what voxel to record for FWER thresholding.                                   |
| pThreshold           | (default=0.05) Voxel-wise threshold.  |
| clusterPerm          | logical (default=FALSE), whether to perform permutation based cluster thresholding.       |
| mask                 | (default=NA) antsImage reference mask used for cluster computations.                      |
| voxindx              | (default=NA) indices of voxels to put in mask   |
| samplemask           | (default=NA) antsImage used to extract voxels back in a matrix.                           |
| clusterPermThreshold |   |
|                      | (default=0.05) threshold for cluster selection after obtaining cluster size distrubution. |
| showInfo             | display info messagges when running the function.   |
| • • •                | other arguments received from lesymap.  |

#### Value

### List of objects returned:

- statistic vector of statistical values
- pvalue vector of pvalues
- zscore vector of zscores
- perm. vector (optional) vector of permuted statistics
- perm.FWERthresh (optional) permutation threshold established from the distribution of perm.vector
- perm.clusterThreshold (optional) permutation threshold established from the distribution of perm.vector

lsm\_regresPerm

#### Author(s)

**Dorian Pustina** 

### **Examples**

```
{
set.seed(123)
lesmat = matrix(rbinom(200,1,0.5), ncol=2)
set.seed(123)
behavior = rnorm(100)
result = lsm_regresfast(lesmat, behavior)
}
```

lsm\_regresPerm

lsm\_regresPerm

### Description

Lesion to symptom mapping performed on a prepared matrix. Regressions are performed between behavior and each column in the lesmat matrix. This function relies on the lmPerm package to run. The number of permutations required to reach stable p-values is established automatically. For this reason, the user cannot specify a predefined number of permutations.

### Usage

```
lsm_regresPerm(lesmat, behavior)
```

### Arguments

lesmat matrix of voxels (columns) and subjects (rows).

behavior vector of behavioral scores.

#### Value

List with vectors of statistic, pvalue, and zscore.

### Author(s)

Dorian Pustina

lsm\_sccan 23

| -            |   |          |
|--------------|---|----------|
| lsm sccan    | Sparse canonical correlations for symptom | mannino  |
| IDIII_DCCUII | sparse canonical corretations for symptom | mapping. |

#### **Description**

Multivariate SCCAN adapted for lesion to symptom mapping purposes. By default an optimization routine is used to find the best sparseness value. If you specify sparseness manually, it will be validated to find the cross-validated correlation that can be obtained with that sparseness. You can skip the entire optimization/validation by choosing optimizeSparseness=FALSE. To understand SCCAN arguments, see <a href="mailto:sparseness=FALSE">sparseness=FALSE</a>.

### Usage

```
lsm_sccan(lesmat, behavior, mask, rawStat = F, showInfo = T,
  optimizeSparseness = T, tstamp = "%H:%M:%S", pThreshold = 0.05,
  mycoption = 1, robust = 1, sparseness = 0.045, nvecs = 1,
  cthresh = 150, its = 20, npermsSCCAN = 0, smooth = 0.4, ...)
```

#### **Arguments**

lesmat matrix of voxels (columns) and subjects (rows).

behavior vector of behavioral scores.

mask antsImage binary mask to put back voxels in image.

rawStat logical (default=FALSE) whether to skip the normalization of values and thresh-

olding at 0.1. If TRUE, the raw voxel weights will be returned.

showInfo logical (default-TRUE) display messages

optimizeSparseness

logical (default=TRUE) whether to run the sparseness optimization routine. If false, the defau sparseness value will be used. If sparseness is manually set this flag decides if the manual sparseness will be checked with cross validations.

tstamp timestamp format used in LESYMAP

pThreshold (default=0.05) If cross validated correlations show significance below this value

the results are considered null and an empty map is returned.

mycoption (default=1) SCCAN parameter, see sparseDecom2 (ddefault=1) SCCAN parameter, see sparseDecom2 robust (default=1) SCCAN parameter, see sparseDecom2 sparseness (default=1) SCCAN parameter, see sparseDecom2 nvecs (default=150) SCCAN parameter, see sparseDecom2 cthresh (default=20) SCCAN parameter, see sparseDecom2 its npermsSCCAN (default=0) SCCAN permutations, see sparseDecom2 (default=0.4) SCCAN parameter, see sparseDecom2 smooth

... other arguments received from lesymap.

24 lsm\_ttest

#### Value

List of objects returned:

- statistic vector of statistical values
- pvalue vector of pvalues
- optimalSparseness (optional) optimal value found for sparseness
- CVcorrelation.stat (optional) Correlation between true and predicted score with k-fold validation using the optimal sparseness value
- CVcorrelation.pval (optional) p-value of the above correlation

### Author(s)

**Dorian Pustina** 

#### **Examples**

 $lsm\_ttest$ 

lsm\_ttest

### **Description**

Lesion to symptom mapping performed on a prepared matrix. T-tests are performed using each column of the matrix to split the behavioral scores in two groups. If var.equal=TRUE the Welch test is performed instead.

```
lsm_ttest(lesmat, behavior, var.equal = T, alternative = "greater", ...)
```

minSegDistance 25

#### **Arguments**

behavior vector of behavioral scores.

var.equal logical (default=TRUE) should the variance between groups considered equal (t-test) or unequal (Welch test).

alternative (default='greater') Sets the expected relationship between voxel value and behavior. By default voxels with zero are not lesioned, and behavior is expected to be higher, thus alternative='greater'. If the relationship in your data is inverted, use alternative='less', and if you don't know your data, use alternative='two.sided'.

other arguments received from lesymap.

··· other arguments received from 100 ymar

#### Value

List of objects returned:

- statistic vector of statistical values
- pvalue vector of pvalues
- zscore vector of zscores

#### Author(s)

Dorian Pustina

### **Examples**

```
{
set.seed(123)
lesmat = matrix(rbinom(200,1,0.5), ncol=2)
set.seed(123)
behavior = rnorm(100)
result = lsm_ttest(lesmat, behavior)
}
```

minSegDistance

minSegDistance

### **Description**

This function computes the metric displacement between two binary masks

```
minSegDistance(manual, predict, get = "all", binarize = F, label = 1)
```

#### **Arguments**

manual manual segmentation of class antsImage, used as reference

predict other antsImage to compare to manual

get (default='all') one of 'mean', 'max', 'min', or 'all'

binarize logical (default=FALSE) whether to binarize the input images

label (default=1) integer or vector of labels to binarize I.e., label=c(2,4) means label

2 from manual, and 4 from predict will be compared.

#### Value

Scalar (for 'mean', 'max', 'min') or list (for 'all'). Note, results are in milimeters

#### Note

max = Hausdorff distance

#### Author(s)

```
optimize_SCCANsparseness
```

Optimization of SCCAN sparseness

### Description

Function used to optimize SCCAN sparseness for lesion to symptom mapping.

### Usage

```
optimize_SCCANsparseness(lesmat, behavior, mask, nfolds = 4,
   sparsenessPenalty = 0.03, lower = 0.005, upper = 0.9, tol = 0.03,
   justValidate = F, cvRepetitions = 3, mycoption = 1, robust = 1,
   sparseness = NA, nvecs = 1, cthresh = 150, its = 30,
   npermsSCCAN = 0, smooth = 0.4, sparseness.behav = -0.99, ...)
```

### **Arguments**

lesmat lesion matrix
behavior behavior vector
mask antsImage mask
nfolds how many folds to use

sparsenessPenalty

penalty term

lower minimum searched sparseness
upper maximum searched sparseness
tol tolerance value, see optimize() in R
justValidate just check the CV of provided sparseness

print.lesymap 27

```
cvRepetitions
```

number of cross-validations standard SCCAN parameter mycoption robust standard SCCAN parameter sparseness standard SCCAN parameter standard SCCAN parameter nvecs cthresh standard SCCAN parameter its standard SCCAN parameter npermsSCCAN SCCAN permutations smooth standard SCCAN parameter sparseness.behav what sparsness to use for behavior

... other arguments received from lesymap or lsm\_sccan.

#### Value

#### List with:

```
minimum - best sparseness value
objective - minimum value of objective function
CVcorrelation - cross-validated correlation of optimal sparness
```

#### Author(s)

Dorian Pustina

the optimization function Will run SCCAN on each training fold, compute behavior prediction on the test fold, and finally return a cross validated correlation from entire sample end of optimfun

```
print.lesymap
print.lesymap
```

### **Description**

Funciton to display some meaningful summary when a lesymap output is called in command line.

### Usage

```
## S3 method for class 'lesymap'
print(x, ...)
```

### Arguments

x the output from a lesymap() call.... useless for compatibility with default print.

### Author(s)

**Dorian Pustina** 

```
registerLesionToTemplate

registerLesionToTemplate
```

#### **Description**

Brings lesion maps in template space by registering the subject\'s anatomical to the template and applying the same transform to the lesion. To improve the registration the anatomical image is bias corrected and denoised. In addition, you can choose to skull-strip the image and run a more careful registration brain-on-brain so that the skull does not impact the registration in any way. Note, for technical reasons the registration is performed counterintuitively by moving the template on the subject, and not the subject on the template. For this reason, to bring the subject in template space we use the inverse transformation. Also note, at the moment ANTsR does not produce an inverse affine transformation explicitly, both forward and inverse affine transforms are identical. You can use ANTs to compute the inverse, or tell ANTsR if you need to invert an affine matrix applying the transformations (see whichtoinvert).

### Usage

```
registerLesionToTemplate(subImg, subLesion, templateImg = NA,
  templateBrainMask = NA, templateRegMask = NA, skullStrip = T,
  typeofTransform = "SyNCC", outprefix = "", tstamp = "%H:%M:%S",
  showInfo = T, ...)
```

#### **Arguments**

subImg antsImage or character filename of the anatomical image of the subject. Typi-

cally this is a T1-weighted MRI image, on which you drew the lesion map.

antsImage or character filename of the lesion map. Typically you draw this manually or obtain it from automated lesion segmentation software. You can try our LINDA toolbox for an automated alternative. Yet, manual drawing can be

performed quickly and is preferred.

templateImg antsImage or filename of the anatomical template image. This image should be

with skull included.

templateBrainMask

antsImage or filename of the template brain mask. This mask is needed for skull-stripped registrations.

templateRegMask

antsImage or filename of the template mask that includes the skull but no face. Useful for improving the skull stripping process.

skullStrip logical whether to remove the skull and perform brain-on-brain registration. typeofTransform

an antsRegistration parameter that controls the quality of registration. The default is SyNCC, which probably is the most robust and takes long (1-2 hours maybe). For faster registration you can try SyN.

outprefix character of the prefix where to save the output. If this is set, most of images and

transformations will be saved at the specified path/prefix. The folder must exist or you will get an error. It is passed without modification to antsRegistration.

tstamp format of the timestamp when displaying info messages.

regresfast 29

```
showInfo logical whether to show info messages or be completely quiet. If you want also verbose registration messages, please set verbose=TRUE.other arguments to pass to antsRegistration
```

#### Value

List of objects returned:

- subImg subject\'s image in native space (after some preprocessing)
- subLesion subject\'s lesion map in native space
- subImgTemplate subject\'s image in template space
- subLesionTemplate subject\'s lesion in template space
- templateImg the template used to register the subject
- templateBrainMask the brain mask of the template image
- subLesionTemplate the template mask with skull and no face
- registration\$inverse\_subject2template transformation matrices subject to template
- registration\$forward\_template2subject transformation matrices template to subject

#### Author(s)

Dorian Pustina

### **Examples**

regresfast

Fast linear regressions

### **Description**

Takes a matrix of voxels and a vector of behavior and runs fast regressions for each voxel. Covariates can be defined (i.e. age) to find the effect of each voxel on behavior within the context of other predictive factors.

```
regresfast(X, y, covariates, hascovar = FALSE)
```

30 save.lesymap

#### **Arguments**

X matrix of voxlels (columns) for all subjects (rows).

y vector of behavioral scores.

covariates matrix with one or more columns. Must be of same length as behavior. This

variable should always be set, and the next argument can tell if covariates should

be used or not.

hascovar logical to tell whether covariates should be used.

#### Value

List with:

• statistic - regression t-score

• n - number of subjects

• kxfm - degrees of freedom.

### Author(s)

Dorian Pustina

### **Examples**

```
set.seed(1234)
lesmat = matrix(rbinom(40,1,0.2), ncol=2)
set.seed(1234)
behavior = rnorm(20)
test = LESYMAP::regresfast(lesmat, behavior, as.matrix(behavior), hascovar=FALSE)
test$statistic[,1] # 0.6915683 1.1434760
test$kxmat # 2
```

save.lesymap

Save the output of lesymap.

### **Description**

Function to save the output of lesymap.

```
save.lesymap(lsm, saveDir, infoFile = "Info.txt", template = NA,
   saveTemplate = F, savePatchImages = T, plot.alpha = 0.8,
   plot.axis = 3, plot.quality = 8, ...)
```

simulateBehavior 31

### **Arguments**

| lsm           | object obtained with lesymap()  |
|---------------|---|
| saveDir       | folder to save to, will be created if it doesn't exist.   |
| infoFile      | (default='Info.txt') what should be the filename of the file with information.  |
| template      | (default=NA) an antsImage to overlay the results to. If the template is provided, results will be plotted and saved as image. |
| saveTemplate  | (default=FALSE) should the template image also be saved? Useful when passing the results to a colleague.                      |
| savePatchImag | ges   |
|               | (default=TRUE) should the patch images be saved   |
| plot.alpha    | see plot.antsImage  |
| plot.axis     | see plot.antsImage  |
| plot.quality  | see plot.antsImage  |
|               | other arguments to use for plot().  |

### Value

Nothing is returned. Files saved include resulting maps and a descriptive file with a lot of information about the lesymap run.

### Author(s)

Dorian Pustina

```
simulateBehavior Simulation of behavior scores from lesion maps
```

### Description

Function simulate behavioral scores based on the lesion load of specific brain areas. Used to run simulation studies.

### Usage

```
simulateBehavior(lesions.list, parcellation, label = NA, mask = NA,
errorWeight = 0.3, binaryCheck = F, exponent = 1)
```

### Arguments

| lesions.list | list of lesions (antsImages) or vector of filenames.  |
|--------------|---|
| parcellation | mask or parcellation image. If a parcellation is passed, lesion load will be computed for each different label (value) in the image. Zero and non-affected labels are not returned by default. The parcellation input can be an antsImage or a character vector pointing to a file. |
| label        | if the parcellation has multiple labels, you can select which labels to simulate behaviors for (i.e., $c(101,43)$ to simulate behavior for labels with value 101 and 43 only)   |

32 simulateBehavior

mask to restrict the count of lesioned voxels. It is not recommended to use

a mask, because lesions should affect behavior as they are, without the user

restricting the lesions to masks defined a posteriori.

errorWeight the amount of error to be added (i.e., 0.5 means half of the simulation will be

error, the other half signal)

binaryCheck check to make sure all lesions are binary

exponent power exponent to elevate behavior in order to increase non-linearity relation-

ship with lesion load. 1 is default, and 3 is what Wang (2013) reported as lesion

load relationship with behavior.

#### Value

List of three objects: - behavload - a matrix of simulated behavioral scores. Each column shows simulation for a single parcel. Column names indicate the label number in the parcellation file.

- lesload same as behavload, but indicates lesions loads from which behavior was simulated.
- lesbehavCorrelation vector of correlation values (Pearson) between lesion load and simulated scores.
